

with access to 1,000's and millions of simulated neurons without resorting to deep learning techniques (ANN_RF).

1. Introduction

Artificial intelligence (AI) has piqued the interest of many academics, researchers, and people working in various industries the efforts and inventions will propel the techniques of AI to success (Alshari and Gawali, 2022a). Machine-learning approaches include neural networks as a subset. They are essentially artificial intelligence systems that mimic connected "neuron units," loosely modeled depending on the way neurons in the brain interact (Yuan et al., 2009). Computational models based on neural connections have been studied since the 1940's.

As computer processing power has increased, large sets of training data have been used to analyze computational models of input data based on neural connections. Since neural networks consist of many ("deep") layers of simulated connected neural-based neurons, AI practitioners refer to these techniques as "deep learning." Before the emergence of deep learning (machine-learning approaches), neural networks typically consisted of three to five layers and dozens of neurons (Girma et al., 2022). There are seven to 10 layers in a deep learning network, each housing thousands of artificial neurons (Alqadhi et al., 2021), and the neural networks work on a feedforward basis. This form of an artificial neural network is the most frequent (Ramdani et al., 2021). This arrangement only passes through the "hidden" levels from the input to the output. There are no loops in the network. In 1958, AI pioneer Frank Rosenblatt proposed the first single-neuron network (Kuemmerle et al., 2013). While the concept is not new, advances in processing power, training methodologies, and data availability have enabled better performance (Alshari and Gawali, 2021a).

A random forest (RF) classifier is a collection or group of classification and regression trees created through random resampling (Alqadhi et al., 2021) of the preparation set on datasets of comparable size to the preparation set, known as bootstraps (Rindfuss et al., 2004; Verburg et al., 2011). When a tree is built as the test set without a specific record from the initial dataset, several bootstraps are used (Shi et al., 2020). The speed of all test sets is developed to measure the speculation error (Alshari and Gawali, 2021b). It is resistant to overfitting and is expected to be more robust in the presence of anomalies and extremely high-dimensional boundary spaces than other AI algorithms (Singh et al., 2021). The SAGA GIS program was used in this study. It is freely available, open-source software. It has an intuitive user interface with various display options and a growing array of geoscientific approaches (Paul et al., 2021).

For the proposed approach (ANN_RF), there are several samples for only six main parameters of class LULC classification for creating model classes. The six parameters are as follows: high land, mountains, land area, built-up (vegetation and agriculture area), and bare land. The

This study developed traditional artificial neural networks with seven to 10 layers using the proposed approach, ANN_RF, with access to thousands and millions of simulated neurons without resorting to deep learning techniques (Khwarahm, 2021). In this study, the neurons consisted of five inputs and three hidden layers. The output was 15 multi-classes from ANN, which was input for implementing the RF classifier that applied big number classes for each parameter of the LULC parameters. Because deep learning has various downsides, such as complexity, expense, and the need to wait longer for results, this creates a significant incentive and impetus to invent and adopt this notion to develop machine learning because it is simple. This study intended to increase the accuracy of machine-learning approaches for land use/land cover classification using Sentinel-2A, Sentinel-2B, and Landsat-8 satellites.

2. Literature review

Several pieces of literature on classifying changes in land use using machine learning methods were reviewed. As demonstrated by earlier research, machine learning is employed (Makwinja et al., 2021) because it is simpler, more adaptable, faster, and less expensive than deep learning and all other artificial intelligence techniques (Alshari and Gawali, 2022b). Deep comprehension problems and algorithms may be complex (Sarif and Gupta, 2021). The combination of object-based and neural-based ANN and RF classifiers has never been addressed, according to the survey results from this study (Xie et al., 2021).

2.1 ANN Classifier

This study covered the literature review about ANN classifier from previous studies as follow: (Mishra et al., 2017; Kadavi and Lee, 2018; Dibs et al., 2020; Dixit and Agarwal, 2020; Ekumah et al., 2020; Hamad, 2020; Kaya and Görgün, 2020; MohanRajan et al., 2020; Navin and Agilandeewari, 2020; Rojas et al., 2020; Saddique et al., 2020; Xu et al., 2020; Angessa et al., 2021; Bhattacharya et al., 2021; Dede et al., 2021; Ghayour et al., 2021; Sang et al., 2021; Xie et al., 2021; Yusof et al., 2021; Ambinakudige and Intsiful, 2022; Fantinel et al., 2022; Gogumalla et al., 2022; Rizvon and Jayakumar, 2022; Theres and Selvakumar, 2022).

The literature review proved that Artificial Neural Network (ANN) is a supervised classification from machine learning based on traditional neural networks that contain limited hidden layers. It has been developed in deep learning using unlimited hidden layers called deep neural networks.

A previous study discovered that employing ANN is limited because of its subpar performance and that the results of applying ANN for classification accuracy vary. It suggests that ANN performs poorly in comparison to other algorithms.

For instance:

the best results.

Implemented SVM and ANN ([Ambinakudige and Intsiful, 2022](#)), with SVM having better results than ANN.

2.2. RF Classifier

This study covered the literature review about RF classifier from previous studies as follow: ([Na et al., 2010](#); [Wang et al., 2011, 2019](#); [Rodriguez-Galiano et al., 2012](#); [Eisavi et al., 2015](#); [He et al., 2015, 2022](#); [Ming et al., 2016](#); [Sonobe et al., 2017](#); [Nguyen et al., 2018](#); [Thanh Noi and Kappas, 2018](#); [Xu et al., 2018](#); [Zhang et al., 2018](#); [Abdullah et al., 2019](#); [Gašparović et al., 2019](#); [Márquez et al., 2019](#); [Ge et al., 2020](#); [Ghayour et al., 2021](#); [Loukika et al., 2021](#); [Rejith et al., 2021](#); [Tan et al., 2021](#); [Tassi et al., 2021](#); [Vignesh et al., 2021](#); [Behera et al., 2022](#); [Girma et al., 2022](#); [Huang and Wang, 2022](#); [Karijadi and Chou, 2022](#); [Matosak et al., 2022](#); [Mwabumba et al., 2022](#); [Sudhakar and Reddy, 2022](#)).

The literature review indicated that the Random Forest algorithm had been widely used in classifying land changes, especially recently. It was superior in most studies in classification accuracy. The classifier's efficiency is due to it being based on an object-based technique. In object-based techniques, due to RF's excellent performance, this study determined that its use is significant, even though its classification accuracy results vary. Nevertheless, all results showed that the RF algorithm is the best machine-learning LULC classifier among the many researched algorithms. In the future, more testing in various climatic conditions will be necessary. Additionally, the findings showed that RF produced trustworthy and extremely accurate land cover maps over large areas with diverse and complicated geomorphologies and little human contact. We classified land use and land cover by comparing RF, ANN, and other classifiers. They discovered that RF performed better than ANN classifiers. For instance, the RF results are better than those from SVM and MLC, according to there and others in 2022 ([Tan et al., 2021](#)).

According to research conducted by [Tan et al. \(2021\)](#), RF outperforms the decision tree classifier, SVM, and ANN ([Ghayour et al., 2021](#)).

In their study published in [Wang et al. \(2019\)](#), discovered that the classification accuracies of RF, SVM, and k-NN were 86.61, 79.96, and 77.23%, respectively ([Xu et al., 2018](#)).

In [Loukika et al. \(2021\)](#), discovered that RF is the best classifier among SVM, RF, and CART in terms of overall accuracy using Landsat-8 and Sentinel-2A ([Ge et al., 2020](#)).

2.3. Multiple (hybrid) classifier approaches

This study covered the literature review about hybrid classifier approaches from previous studies as follows: ([Malinverni et al., 2011](#); [Wang et al., 2011](#); [Kumar et al., 2013](#); [Márquez et al., 2019](#); [Munthali et al., 2020](#)).

the Complete Ensemble Empirical Mode that combines random forest (RF) with Long Short-Term Memory (LSTM; [Wang et al., 2011](#)).

Furthermore, [He et al. \(2022\)](#), carried out research on a hybrid deep-learning-based recurrent model (DGRN) to map the water clarity of worldwide lakes using Landsat-8 Operational Land Imager (OLI) pictures ([Malinverni et al., 2011](#)).

[Huang and Wang \(2022\)](#) created hybrid landscapes ([Munthali et al., 2020](#)) with enough cooling intensity to reduce the UHI effect successfully.

[Wang et al. \(2011\)](#) completed their work ([Márquez et al., 2019](#)) of using a hybrid technique combining supervised classification and principal component analysis (PCA) to identify dandified land changes.

Malinverni et al. ([Kumar et al., 2013](#)) presented a hybrid classification method. Compared to traditional pixel-based approaches, the suggested hybrid methodology allows for extracting additional LULC classes while significantly increasing classification accuracy. However, it is challenging to combine many classifiers. The limited literature indicates that more research on hybrid tactics is needed. It has been noted that the efforts to use mixed techniques are insufficient ([Lo and Choi, 2004](#); [Schepaschenko et al., 2011](#); [Mahiny and Clarke, 2012](#); [Singh et al., 2014](#); [Vignesh and Thyagarajan, 2014](#); [Vignesh et al., 2016, 2022](#); [Sturari et al., 2017](#); [Vignesh and Thyagarajan, 2017](#); [Mishra et al., 2018](#); [Thyagarajan and Vignesh, 2019](#); [de Deus et al., 2021](#); [Regasa et al., 2021](#); [Wambugu et al., 2021](#); [Behera et al., 2022](#))^{1,2}.

After 2000, hybrid approaches gained popularity. It was frequently used for classifying land cover. Research into hybrid classifiers is still needed to maximize the categorization accuracy of Landsat-8 pictures. They are regarded as more involved methods of classifying land cover. Because each classification system has benefits and drawbacks, choosing the best one can be challenging. For instance, the performance of supervised algorithms like maximum likelihood will improve with sufficient training points and normally distributed image data. However, such methods cannot yield reliable results in complex environments, necessitating additional methods like hybrid approaches. Early hybrid techniques, which began in the 1980's, soon after the development of supervised and unsupervised classification, were built using Landsat-8 images. However, the hybrid system has become more adaptable and potent because of enhanced classifiers.

3. The proposed approach

First, although this study used a multi-layered ANN, the initial neural networks only included five input levels and three hidden layers, and they only produced results for a single class.

There were six fundamental parameters, each of which had several types. There were 5,000 samples and 100 trees for constructing model classes for six primary parameters: high land,

output layer. The input layer received the input signals and passed them on to the next layer, which then delivered the final prediction to the output layer.

The task at hand, perceptron, was a multi-layered perception system. A perceptron is made up of numerous neurons, which are the fundamental building blocks of the brain. Each circle symbolizes a neuron in simple terms. Perceptrons are a dense layer of vertically arranged neurons. One can now see each neuron in the image from a detailed perspective. Weights (w_1 , w_2 , w_3) and biases were assigned to each neuron, and computations were carried out as follows:

$(F = w_1 * x_1 + w_2 * x_2 + w_3 * x_3)$, combination = bias + weights * input.

The input layer received the data first and then sent it to the hidden layers, where the interconnection between the two layers assigned weights to each input randomly. After bias was applied to each input neuron, the weighted total, a combination of weights and preferences, was conveyed through the activation function. The activation function determined which node should be used for feature extraction and then computes the output. The model weights were adjusted, and the prediction process was finished. The input node converted the data into numerical form. Each node was allocated a number, which denoted an activation value. The higher the number, the more intense the action.

The activation value was transferred to the next node based on weights and the activation function. Each node calculated and updated the weighted total (activation function) depending on the transfer function. It then performed a process called activation. This neuron was the only one that can perform this function. These nodes then chose whether or not to transmit the signal. The ANN adjusted the weights, which determined the signal extension. The activation traveled across the network until it reached the destination node.

Afterward, the RF classifier received the output ANN. The steps in the random forest approach were as follows: A random forest selected n random records from a dataset of output ANN records at random. Individual decision trees were created for each sample. Each decision tree generated a result. The simplest random forest with random features was made by randomly splitting a limited set of input variables at each node. Combining the work ANN classifier with the work RF classifier, the study concluded that ANN_RF and worked hyperparameters yield the best split.

Finally, the suggested method sought to merge RF hyperparameters with ANN hyperparameters. [Figure 1](#) shows hybrid artificial neural networks (ANN_RF).

Figure 1

www.frontiersin.org
(<https://>

Figure 1. A workflow diagram for proposed work hybrid artificial neural networks (ANN_RF).

Because of the merging of the two neural-based and object-based approaches, the number of layers in ANN_RF accessed thousands and millions of simulated neurons. The input to the RF classifier was the implementation of this novel method in software SAGA *via* the outputs of the artificial neural network. Then, rather than a single tree, each tree was built individually using the features of packing and randomness to produce a forest unrelated to what the trees expected.

4. Implementation of hybrid artificial neural networks (ANN_RF)

The process was conducted for LULC classification using the proposed classifier ANN_RF. It was provided at the outset of the study area data and was obtained afterward from multispectral satellites, Landsat-8 and Sentinel-2A satellites. This stage of preprocessing will be described in depth in the following section. LULC classification was done with SAGA software using the proposed classifier (ANN_RF) following its accuracy assessment. We used a change matrix with a polygon/grid in this study. We found LULC classification for Sana'a city with Landsat-8 resolution 30 m following in the down and sentimental-2A satellite. The fundamental parameter used in this study included six parameters: rocky area, mountains and high land, roads and land area, built-up area, vegetation, bare land, and agricultural area (see [Figure 2](#)).

4.1. Study area

Sana'a is Yemen's capital, the Sana'a governorate. It is situated at the height of 2,150 meters above sea level, on the equator's north line (15–21) and Greenwich's longitude (12–44) east ([Bhattacharya et al., 2021](#)). It is surrounded by two mountains (Jabal Naqum on the east and Jabal Eiban on the west) and the province ([Bhattacharya et al., 2021](#)). The city offers a unique environment around 2,200 meters above sea level ([Angessa et al., 2021](#)). Sana'a is

Figure 3. Location map of the case study.

4.2. Data collection

Images from a scientific agency in the Sana'a region were utilized in this investigation. The base map (Navin and Agilandeewari, 2020) was created from survey pictures of the toposheet at a scale of 1:50,000. The data used in the current study were collected from the Landsat-8 satellite, which was launched in 2016. The calibration and comparison procedure for modifying land was made possible due to the 2016 data collected in December. In this study, the Landsat-8 satellite dataset contained 12 images, as shown in Table 1. Photos from a scientific agency in the Sana'a region were used in this investigation.

For the case study, multispectral pictures from Sentinel-2 and Landsat-8 were available (Figures 5, 6), demonstrating the preprocessing corrections for band 432. Valid data with geometric and radiometric corrections were included in the preprocessing. These processes improved satellite imagery for categorization and corrected degraded images to produce a more accurate scene representation.

4.4. LULC classification

[Download\(/articles/10.3389/frai.2022.964279/pdf?isPublishedV2=False\)](https://www.frontiersin.org/articles/10.3389/frai.2022.964279/pdf?isPublishedV2=False)

This section explains the methodology applied in the general-level LULCC land use planning for Sana'a city and the specific findings derived using multispectral medium-resolution satellite data. Our analysis suggested that the LULC in Sana'a saw significant changes in 2016.

parameter had several different types. [Table 2](#) shows 5,000 samples and 100 trees for six critical factors used to create model classes: high land, mountains, land area, built-up vegetation, and bare area land, with many subclasses, i.e., notes on SAGA software parameters. The categorization in these models was seven, but the processing and results in the parameter were six because merging area vegetation with farmed land created six classes. We created samples based on RGB color composites of Sentinel-2A photos, such as the vegetation class (red pixels in RGB = 432), which showed detailed changes in the region. For the proposed (ANN_RF) approach, numerous samples (hyper-parameter samples) of only six main parameters of the LULC classification were used to create model classes with detailed changes in the region. [Figures 7, 8](#) are two different views of the same place.

Figure 8. Classification of land use land cover with proposed work (ANN_RF).
Downloaded from <https://www.frontiersin.org/articles/10.3389/frai.2022.964279/pdf> published 02 February 2023

The types of hyperparameters used in this proposed model are `max_sample` and `bootstrap`. It improved the algorithms of machine learning (ANN and RF) with the help of the ANN_RF model, where types of hyperparameters of RF are as follows: `max_depth` in a random forest, the longest path between the root node and the leaf node was defined as the tree's maximum depth, `min_sample_split`, a random forest decision tree's minimum needed the number of observations in each node specified by this parameter; default = 2, `max_leaf_nodes`. These hyperparameters limited the tree's growth by requiring the splitting of nodes in the tree, `min_samples_leaf`. After splitting a node, this random forest hyperparameter set the minimum number of samples in the leaf node. Default = 1, estimators, the forest's total number of trees, `max_sample`; the max samples hyperparameters controlled how much of the original dataset was allocated to each tree, `max_features`; this was comparable to the maximum number of features offered to each tree in a random forest, the data point sampling method with or without replacement, and the criterion, the function for assessing the split's quality. The criteria "Gini" for Gini impurity and "entropy" for information gain were supported.

5. Evaluation of the ANN_RF model's performance

The proposed model's temporal complexity evaluated the ANN_RF model's performance. This study demonstrated that the proposed use of ANN_RF is a means to improve performance (both speed and accuracy). The time complexity of the (ANN_RF) model has three stages: First, the time complexity for ANN is calculated by the formula in Equation 1 (see text footnote ¹). It shows the training time (in seconds) with ANN. As a result, the focus of ANN enhancement was on parameters and layers.

$M_{ij} * M_{jk}$ is simply $O(i * j * k)$ (1) (time complexity for ANN) (see text footnote ¹).

Then, it showed the time complexity in the case of RF. The time complexity for RF of constructing a complete unpruned decision tree was governed by Equation 2 (see text footnote ²), where n was the number of nodes in the tree: $O(v * n \log(n))$ (2) (time complexity for RF) (see text footnote ²).

In the proposed technique, we merged the limited parameter (ANN) + hyperparameter (RF) = hyperparameter (ANN_RF) model in the proposed approach. It showed the time complexity of the proposed model, ANN_RF, with improved accuracy as 0.2 s, 0.3 s, 0.4 s, and 0.5 s. In the best case, the ANN_RF model had better time complexity than Equation 3, which was derived from Equations 1, 2, as shown below:

We explained the driven equation time complexity for (ANN_RF) model using a common extract factor between Equation 3 (time complexity for combination ANN + RF).

Download/articles/10.3389/frai.2022.964279/pdf?isPublishedV2=False

$$[O(v * n \log(n)) * (O((i * j * k)^2))] \quad (3)$$

$$O[(v * n \log(n) * ((i * j * k)^2)] \quad (4)$$

$$O((v * n \log(n))((i * j * k)^2)). \quad (5)$$

On the other hand, a random forest randomly selected the rows and characteristics of the dataset using a bootstrapping technique. This randomization allowed a tree to have only a few samples and features while ensuring that all models and elements were considered in the other trees, restricting overfitting. The field determined the algorithm's output with the most votes in the event of a category variable and the average of all possible outcomes in the case of a numerical variable after generating several trees with different characteristics and samples.

It trained the model with many trees (for example, 1,000 trees) and then chose the best subset of trees to adjust the number of layers available to the ANN_RF trees. It was unnecessary to train a fresh random forest with different tree numbers each time. Slower learning is associated with higher accuracy. We reduced the number of estimators and increased the number of trees in the model to speed up the random forests.

6. Results

Tables 3–5 showed that the (ANN_RF) approach outperformed an ANN classifier using two satellites, Sentinel-2A and Landsat-8, better than the ANN classifier. This study successfully implemented the novel technique (ANN_RF). The result showed that improved classification accuracy for land use and land cover is possible. This study also found the proposed work for building machine learning with the overlap of entering ANN output into object-based approaches through the RF classifier to be practical. It was judged to be a high-accuracy classifier that enhanced ANN when it was single. Tables 4, 5 showed that ANN gave zero value in some classes, while (ANN_RF) gave some value to them. Further, the percentage of identified types in (ANN_RF) was better than in ANN.

Table 5. Area and percentages LULC for ANN and (ANN_RF) to Landsat-8 satellite.

There are elements affected by the results of land change classification and three factors:

- i) Type of resolution satellite.
- ii) Type of artificial intelligent classifier.
- iii) Region types from the land use and land cover of the land selection. The processing stage is different from one classifier to another.

Every classifier in AI for land change classification has a process for running the algorithm.

7. Accuracy assessment

The confusion matrix and the A kappa coefficient were used for accuracy evaluation. A confused matrix of perplexity (sometimes called an error matrix) indicated how well a classification model or a classifier performed on a set of test data with known appropriate values (Ge et al., 2020). A confusion matrix was a tool for comparing the differences

confusion matrix. The confusion matrix's results were divided into four groups. [Tables 6–9](#) show that each group encompasses five categories of 2016 results. In this study, the SAGA GIS software used for LULC classification automatically created a confusion matrix and kappa coefficient with Excel for statistical computing values and overall accuracy, and the LULC image's kappa coefficient is shown in [Table 3](#).

8. Discussion

Feature extraction from multispectral satellites is varied, such as being cheap, being free, covering a large region, and being more readily available. Additionally, the spectral bands in each image captured by multispectral satellites, as well as the spectral bands deduced from them, enabled us to access “hidden” data about features or objects that are used for image preprocessing, such as land use treatment, land cover classification, and more; however, it could not be detected. The features obtained from this study from the supplied satellite images—spatial, spectral, and spatial-spectral features—were retrieved.

An efficient method for analyzing texture features is the local binary pattern (LBP) method. It combines the advantages of statistical and structural approaches for texture analysis. Further, it increases the accuracy of machine learning approaches for land use/land cover classification using Sentinel-2A, and Landsat-8 satellites because deep learning has various downsides, such as complexity, expense, and the need to wait longer for results; this creates a significant incentive and impetus to invent and adopt the notion of developing machine learning approaches because it is simple.

We compared the outcomes of our suggested model with various other combinations, such as RF+SVM, MLC+SVM, and ANN+SVM, to assess the performance of the proposed method. We used two distinct satellite photos in this study. For our experiments, we specifically used Sentinel-2A and Landsat-8 satellite pictures. The Gabor filter extracts the crucial texture features from the raw image during the feature extraction stage.

For the supervised classification algorithm (object based) to classify data into various land use and land cover classes with ease during the classification phase. It was discovered that our suggested method produces results with greater accuracy than other methods. Finally, a clever edge detection algorithm separated the classes of land use and land cover from the LULC.

We discovered that combinations of classifiers had been discovered. However, we could not locate an ANN-RF classifier combination in the land use and land cover classification field. This shows that the scientific gap that was studied in this study has not yet been filled ([Vignesh and Thyagarajan, 2014](#); [Vignesh et al., 2016, 2022](#); [Vignesh and Thyagarajan, 2017](#); [Thyagarajan and Vignesh, 2019](#)).

Despite the advent of advanced technologies that have appeared over time for increased classification accuracy outcomes, this study recommends that future users and researchers continue research into the development of machine learning approaches. Further, it is recommended that researchers continue experimenting with merging these RF and ANN algorithms with other satellites and other time and environmental conditions. Through the aforementioned clarification, it is evident that this study's findings differ significantly from those of the earlier studies described in the literary survey part; this shows that the scientific gap studied here has not yet been bridged.

Data availability statement

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/supplementary material.

Ethics statement

Written informed consent was obtained from the individual(s), and minor(s)' legal guardian/next of kin, for the publication of any potentially identifiable images or data included in this article.

Author contributions

All authors listed have made a substantial, direct, and intellectual contribution to the work and approved it for publication.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.
